The article considers basic principles for designing optimal cycles for internal grinding in a multidimensional space of controlling parameters: axis feed rate, radial feed, etc. For the first time in order to optimize machining process we used such mathematical optimization method as a method of dynamic programming. Its application allows to take into account the full range of technological limitations (on the allowable error of size, on the allowable depth of burn mark and etc.), as well as to replace the exhaustive search of solutions by the targeted one. This reduces the costs and time it takes at manufacture for selection of the optimal characteristics of processing conditions.

Keywords: internal grinding, optimization of machining process, cycles, dynamic programming.
